Description

Technical Field

- 5 [0001] This invention relates to exchanging data over a telecommunications network, and more particularly to customizing the application protocol by which users of a telecommunications network communicate with the network.

Background of the Invention

- 10 [0002] As telecommunications network subscribers seek to optimize their use of the many electronic communication services available to them, there is an increasing demand for networks that can be customized to fit each subscriber's particular needs. Currently, most communications are performed over public networks using standard communication protocols.

- 15 [0003] The standard communication protocols that are used on most public networks consist essentially of a set of coding rules that characterize the data to be exchanged over the networks.

[0004] Once the rules are known, data can be encoded and decoded by network users without ambiguity. A drawback of using standardized protocols is that they cannot be redefined and/or customized according to a user's individual needs without making changes to the user's software.

- 20 [0005] The current state of the art in telecommunications requires network users to modify their software to accommodate changes in the communication protocols. For example, a bank may have a system in place that allows its customers to request account information over the telephone. The bank's system prompts the customer to select a service and the customer depresses one or more Touch Tone™ buttons to supply a response. The bank's computer is programmed to carry out one or more steps in response to each customer request, such as sending a fax when the customer enters a "1", or sending a voice message when the customer enters a "2". This type of system, however, is limited to the preprogrammed responses contained in the bank's software. If the bank would like to modify its system to handle new types of information requests, the bank would have to modify the system software accordingly. One way around this problem would be to have a network operator (such as AT&T) provide an adaptable interface between the customer and the bank. An adaptable interface would allow users to redefine the form of their business communications without incurring the losses of time and money normally associated with modifying their network interfaces. Accordingly, a capability to customize protocols is highly desirable to network users, and, in turn, to the network operators seeking to attract those users.

- 25 [0006] EP-A-0 621 714 discloses a system for reducing the cost of calls, typically 800 number calls to an information source, by transforming a voice connection at an originating toll switch into a data connection to the desired information source. The toll switch is coupled to a service platform including a plurality of Universal Access Nodes (UAN) linked to the information source via a packet network and a service node. When a call is received by the platform, the calling information includes a Dialed Number Identification Service which identifies the type and/or origin of the call. The UAN identifies the requested service and the identity of the information source. The UAN presents to the caller an application interface that the information source would normally present to the caller. An access module in the UAN converts the caller voice signal into a digital signal. An associated CPU translates the digital signal into a message for transmission over the packet network to the service node which unbundles the message and interfaces with the information source. The service node forms a message from the information provided by the information source for return to the platform via packet network. The CPU working in conjunction with the access modules removes the requested information for transmission to the caller in the format requested by the caller.

- 45 Summary of the Invention

[0007] A method and apparatus according to the invention are as set out in the independent claims. Preferred forms are set out in the dependent claims.

- 50 Summary of the Invention

- [0008] In accordance with the present invention a network service subscriber (such as a bank) tells the operator when an incoming message from a caller is expected and the format in which that incoming message should be placed. The operator then translates the caller's message into the subscribers's format before relaying the message to the subscriber. In the same fashion, the subscriber tells the operator when the subscriber expects to send an outgoing message to the caller and the format in which outgoing messages will be placed. The operator translates the outgoing message into a format the caller understands before relaying the message to the caller. In this manner, the dialog between the subscriber and the caller can be varied without modifying either party's interface software. The advantages

of such a system are illustrated in the banking example set forth below.

[0009] By using the present invention a bank may readily customize the communications carried on between the bank's computer and the bank's customers. The bank's computer would be provisioned with interface software designed to operate with the present invention. Thereafter, to change the bank-customer communication flow, the bank would inform the network operator of any new types of customer requests that the bank intends to answer, the possible responses to those requests, and the format of the requests and responses. The network operator would then use the information provided by the bank to modify a database containing the bank-customer communication protocol. The implementation of the new communication flow is complete after the database is edited. Thus, the implementation of a new bank-customer communication flow involves the mere editing of a database, and neither the bank nor the network operator need modify their respective software.

[0010] In a preferred embodiment of the invention, a network operator uses a Customer Transaction Profile (CTP) Database to store current "protocol definitions" for each subscriber (e.g. the bank). This database is stored on computer disk and may be edited at any time to reflect redefinitions of the stored protocols.

[0011] To setup a protocol, a subscriber provides the network operator with the specifications of the subscriber's desired protocol. Using these specifications, the operator makes the necessary entries in the CTP database to enable customized communication. The subscriber's CTP file may be edited at anytime. Thus, a subscriber desiring to implement a new protocol simply provides the operator with new specifications which the operator then uses to edit the CTP file and thereby change the protocol.

[0012] When communication with a subscriber is initiated by a caller, the subscriber's CTP file is loaded from the disk memory into one of the network's "front end systems" for execution. The front end system reads the file to determine an input message format and an output message format, and then uses these formats to translate communications to and from the subscriber, respectively. Messages sent from the caller to the subscriber pass through the front end system where they are converted into the form specified by the input message format. Messages sent from the subscriber to the caller are sent in the output message format and converted by the front end system from the output format to a format that the caller can understand.

[0013] Using the front end system as a translator allows subscribers and callers to change the form of their communications without changing their respective network interfaces. Also, using the CTP to store protocol definitions allows subscribers' protocols to be changed without changing the software programs resident at the front end system.

Brief Description of the Drawings

[0014]

FIG. 1 is a block-schematic diagram of an illustrative communication system incorporating the present invention. FIG. 2 is a block-schematic diagram of a communication system incorporating a preferred embodiment of the invention.

FIGs. 3A and 3B make up a flow chart depicting the sequence of operations according to the invention.

FIG. 4 is a block-schematic diagram showing a configuration of software modules and network servers that may be used to implement a preferred embodiment of the invention.

Detailed Description

[0015] FIG. 1 is a block diagram of an illustrative embodiment of the present invention. As shown in the figure, the illustrative embodiment includes a subscriber 10, a front end system 12, a network 17, and a caller 18. The front end system may be part of the network or it may be separate from the network, and it may take the form of an electronically automated device such as a personal computer, computer workstation, mainframe computer, or microprocessor. For illustrative purposes the front end system is shown in figures 1 and 2 as being separate from the network. The software necessary to implement the invention is stored in the front end system. This software makes use of data located in a Customer Transaction Profile database (CTP) 15 which is located in a disk memory 14 of the front end system 12.

[0016] The CTP contains a separate record for each network subscriber. This record contains instructions concerning how the subscriber wants to communicate over the network at the application software level. Whenever a communication with the subscriber is initiated, front end system 12 accesses disk memory 14 to locate the subscribers CTP record. The record is then loaded into a main memory 16 of the front end system so that the record can be used to control the initiated communication session. Since the CTP contains all the necessary information to implement each subscriber's application protocol, varying the protocol merely requires editing the CTP.

[0017] In a preferred embodiment the CTP setup procedure involves the following steps. First, the subscriber's business transaction flow and the "business data" to be exchanged over the interface between the network element and the subscriber's equipment is analyzed. The results of the analysis are recorded into a "business transaction form,"

defined by the network operator. The purpose of this form is to ensure adequate information for later use and to prevent potential ambiguity. Second, the services (actions) that the network operator will perform to add values and help complete the subscriber's business transaction(s) are identified. The codes for these services/actions are obtained via a "services/actions handbook" provided by the operator (the specific services provided and the way they are activated are beyond the scope of the present invention). Third, the business transaction form is completed by associating appropriate services/actions codes with "each" step of a business procedure. Following the third step, the business transaction flow is stitched together and the associated telecommunication services are lined up, ready for use in executing the subscriber's transaction flow. Finally, the subscriber is assigned an identification number, or "ID number".

[0018] A technician "converts" the data recorded in the business transaction form into a Customer Transaction Profile (CTP) using computer software tools and by entering the data into a provisioning system, a computer system separate from the front end system. The provisioning system formats the Profile into a file associated with the subscriber's ID number and downloads that file into a front end system. The Profile, after being downloaded into the front end system, is "indexed" by the system's advanced intelligent software package for use in processing messages associated with the subscriber's ID number. The technician then "turns on" the customer transaction profile in the front end system and the subscriber is "on-line." Once the subscriber is turned on, the network operator executes the subscriber's business transactions according to the agreed upon business data flow.

[0019] Messages received by the front end system stimulate the intelligent software package to open the appropriate subscriber Profile as determined from the subscriber ID number. The messages are "decoded" according to the message specifications recorded in the profile. Network services are then activated by the instructions embedded in the messages to add values to the subscriber's business transactions. If the subscriber decides to change the business transaction flow, a new business transaction form is generated, and the information contained in the form is reflected into the subscriber's Customer Transaction Profile. While the CTP is being modified, the existing profile may be "locked" so that it is not referenced for call processing before modification is completed. When modification is complete the new Profile is turned on and may thereafter be used to process calls.

[0020] As an alternative to having a technician update the CTP 15, updating may be done directly by the subscriber 10 via a communication coupling 20. Coupling 20, as well as all other communication couplings associated with the invention, may be an existing coupling or a customized coupling; and may be in the form of any of the known types of communication couplings, such as a standard telephone line, a twisted shielded pair line, a coaxial cable, a fiber optic link, or a wireless link.

[0021] Once the CTP record is setup for a subscriber the communication flow between the caller 18 --any telecommunications device-- and the subscriber 10 can proceed. The caller initiates a communication by sending a signal over coupling 22 to network 17. The network is coupled to front end system 12 via coupling 30. The front end system 12 determines which subscriber the call is directed to and loads that subscriber's CTP record into main memory 16. The front end system translates the caller's message into an input format that is specified in the CTP record and then transmits the translated message to the subscriber over coupling 24.

[0022] If a reply from the subscriber is required, the subscriber transmits the reply to the front end system over coupling 26. The reply is in an output format that is specified in the subscriber's CTP record. The front end system translates the reply from the output format into a format that can be understood by the caller. Once translated, the reply is transmitted to the network over coupling 32 and is relayed to the caller via coupling 28. This information loop from caller 18 to subscriber 10 and back to caller 18 may be traversed many times during a communication session.

[0023] In a preferred embodiment, depicted in FIG. 2, a customer will make requests from a bank's computer by using Touch Tone™ buttons 64a-64i on the customer's phone. Referring to FIG. 2, there is shown a bank computer 40, a front end system 50, a network 58, and a bank customer 62. Also depicted in FIG. 2 are block diagram representations of an input message 48 and an output message 66. The input message is in the input message format, the format into which the front end system will convert messages directed from the customer to the bank computer. The output message is in the output message format, the format in which the bank computer will send messages to the customer. The front end system must convert the bank computer's output message from the output message format to a format that the customer can understand.

[0024] A typical transaction between the bank 40 and the customer 62 would proceed as follows. The customer dials "ABC Bank's" service hot-line. The customer is connected to the network through a standard telephone coupling 60. The network then connects the customer to the front end system - via coupling 55 - so that the front end system can perform the front-end business interactions for the ABC Bank 40. A software function in the front end system is activated and the dialed number is mapped to a "subscriber ID number" to uniquely identify ABC Bank's CTP record 56. The Bank's CTP record is then read from the front end system's disk memory 52 into the front end system's main memory 54 for active operation.

[0025] A sample CTP record to be used in the present illustration is shown in Table I.

[0026] The front end system software reads the first instruction specified in the customer's CTP record to start the "business transaction execution". Referring to the CTP record shown in Table I, this first instruction would be an an-

nouncement, ABC-0. ABC-0 is played to the customer 62:

(voice) You have reached the ABC Bank's customer service hot line, please make your selection from the following menu:

For your account information, press 1.
For an interest rate update, press 2.
For fund transfer between accounts, press 3.
To end the call, press 0.

[0027] The customer makes a selection by pressing one of the Touch Tone™ buttons 64a-641 on the customer's telephone. In the present example, the customer selects #1.

[0028] The front end system software then plays an announcement, ABC-1-1, according to the business transaction direction recorded in the CTP record:

(voice) Please enter your account number.

[0029] The customer responds with the desired account number.

[0030] The front end system software then plays an announcement, ABC-1-2:

(voice) Please enter your PIN number.

[0031] The customer responds with the PIN number.

[0032] At this time, the front end system software identifies the ""0" sign from the CTP record. The "" indicates that an input message is expected by the ABC Bank and that the ABC Bank will send a reply. The "0" indicates that the front end system should go back to instruction ABC-0 and play the main menu again.

[0033] The front end system formats an input message 48 according to the input message format, ABC-1-2, specified in the customer's CTP record. Two lines within the CTP record define the ABC-1-2 format; the first line, "ABC-1-2: (2,2,10,10)", setting forth a field size for each field in the format, and the second line, "Query Bank, selection, account #, PIN #)", setting forth a field definition for each field in the format. The field sizes are used by the front end system to formulate an input message "packet" by which the information from the customer is relayed to the bank. The field definitions may be "looked up" by the front end system in a protocol dictionary to determine what action, if any, the front end system should take regarding a particular input or output message.

[0034] One way the protocol dictionary may be implemented is through a "look up table", in which each field definition is cross referenced to a computer readable code. A more detailed discussion of the protocol dictionary is not necessary to completely describe the present invention, and is therefore beyond the scope of this application.

[0035] In any event, input message format ABC-1-2 consists of the following fields: an X.25 header 68, 2 bytes indicating a data base query 70, 2 bytes indicating the customer's selection 72, 10 bytes representing the customer's account number 74, and 10 bytes representing the customer's PIN number 76. The X.25 header enables the input message "packet" to be transmitted over coupling 46 using the X.25 packet switching protocol. It should be understood that although the X.25 protocol is used in the described embodiment, there are many other well known protocols, such as the Integrated Services Digital Network - Primary Rate Interface (ISDN-PRI) protocol, that may be used to implement the invention. It should also be understood that the size of each field (number of bytes) can be customized for each subscriber.

[0036] After receiving the input message 48, the bank computer 40 queries its database 42 and formats an output message 66 according to the output message format 15, specified in the bank's CTP record. The output message consists of: an X.25 header 78, 2 bytes containing a code indicating the front end system service to be performed 80 - in this example number 15 means text to speech, 8 bytes indicating the transaction ID 82, 4 bytes indicating the length of the text to be converted 84 - in this example XX bytes, and XX bytes containing the text to be converted 86. As was the case with the input message, an X.25 header is needed to transmit the output message "packet" using the X.25 packet switching protocol. The output message is transmitted over coupling 44.

[0037] Following transmission of the output message 66 from the bank computer 40 to the front end system 50, the front end system converts the account information 86 into speech and plays the speech to the customer 62 via coupling 55, network 58, and coupling 60. The front end system then plays the main menu, ABC-0, as directed by the "0" in the ""0" indication.

[0038] The customer selects #3 to transfer funds from one account to another account.

[0039] The front end system collects the customer's input and plays an announcement, ABC-3-1:

(voice) Please enter the account number you wish to transfer funds from.

[0040] The customer enters the "from" account number, XXXXXXXXX.

[0041] The front end system then plays an announcement, ABC-3-2:

(voice) Please enter the account number you wish to transfer fund to.

[0042] The customer enters the "to" account number, YYYYYYYYY.

[0043] The front end system requests the customer to enter the amount to be transferred, ABC-3-3:

(voice) Please enter the amount to be transferred.

[0044] The customer enters the amount, ZZZZ.

[0045] The front end system identifies the "4" sign from the CTP record. In response to the "" indication, the front end system formats an input message according to the ABC-3-3 input format specified in the CTP record (NOTE: the ABC-3-3 format is not depicted in FIG. 2). As shown in Table 1, the ABC-3-3 format consists of: 2 bytes indicating a fund transfer, 2 bytes indicating the customer's selection, 10 bytes indicating the "from" account number, 10 bytes indicating the "to" account number, and 10 bytes indicating the amount to be transferred. The bank computer performs the fund transfer and sends a text-to-speech message to the front end system according to output message format 15. The front end system relays the speech to the customer and then responds to the "4" indication in the "4" sign.

[0046] In response to the "4" indication, the front end system announces ABC-4 to the customer:

(voice) If you need fax confirmation, press 1.

If you need paper mail confirmation, press 2.

[0047] The customer selects 1 and the front end system requests the customer to enter the phone number for the fax confirmation by playing the announcement ABC-4-1:

(voice) Please enter the fax number with the area code. This will result in a \$1.00 charge to your account you transferred funds to.

[0048] The customer enters the fax number. The front end system identifies the "0" sign and formats an input message to the bank according to the ABC-4-1 input message format. The message takes the form of: 2 bytes indicating a fax confirmation, 2 bytes indicating the customer's selection, and 10 bytes indicating the customer's fax number. The bank then instructs the front end system to originate an output message in output message format 16. The first 2 bytes of the output message indicates the service to be performed by the front end system - in this case #16 indicates text-to-fax service. The next 4 bytes indicates the length of the text to be converted - in this case XX bytes. The last XX bytes contain the text to be converted.

[0049] The front end system plays the main menu again, in response to the "0" indication in the "0" sign and the sequence of operations continues according to the profile.

[0050] FIGs. 3A and 3B make up a flow chart that shows the steps taken by the front end system in processing communications with the subscriber. As shown in FIG. 3A, the front end system must first obtain a transaction request from the transaction manager (step 120). Such a request will be generated whenever the CTP record indicates that an input message will be sent to the subscriber from the front end system, or that an output message is to be sent from the subscriber to the front end system. After receiving a transaction request, the front end system queries as to whether or not a new transaction is being initiated (step 122). If a new transaction is being initiated, the CTP record associated with the transaction must be loaded into the front end system's main memory, or "processing buffer" (step 124). If the transaction request is part of an old transaction, it may be processed using the CTP record currently in the processing buffer.

[0051] Once the correct CTP record is loaded into the processing buffer, the front end system proceeds to identify the message type called for by the request, either an input message or output message (step 126). After the message type is identified (step 126), the appropriate processing "branch" is entered (step 128).

[0052] When an input message is requested, the input message branch is entered and the front end system takes the following steps. First, the front end system collects the business data to be sent to the subscriber (step 130). In the bank-customer example, the business data to be sent might be a bank account number. Next, the business data is then formatted according to the input message format supplied in the CTP record (step 132). The interface handler is then activated and the input message is sent to the subscriber (step 134). At this point front end system processing of the input message is complete (step 136).

[0053] When an output message is requested, the front end system enters the output message "branch" of the flow chart. As a first step in processing an output message, the front end system reads the service code from the output message (step 138). Based on this service code, the front end system accesses the CTP record and locates the corresponding output message format. The front end system uses its knowledge of the format to parse the business data from the output message (step 140). It then activates any network servers that it will need to carry out the service requested in the output message (step 142) and collects responses from those servers (step 144). At this point, the front end system inquires as to whether or not an input message will immediately follow completion of the output message service (step 146). If an immediate input message is required, the input message branch will entered. If an input message is not required, the front end system's processing of the output message is complete (step 148).

[0054] FIG. 4 shows one configuration of front end system software modules and network servers that may be used to implement the present invention. As shown in FIG. 4, the interface between a subscriber and the front end system includes two software modules, an interface handler 90, and a transaction manager 92. The interface handler performs the signal processing necessary to enable the front end system to communicate using standard Open Systems Interconnection (OSI) protocols. The transaction manager performs the task of identifying the subscriber associated with each transaction request.

[0055] After each transaction request has been associated with a subscriber, the nature of the requests are documented by a transaction request parser 94. This documentation is used by an Input/Output message analyzer 96 to access the CTP 98 and obtain the information necessary to process the request. If the request requires the collection or generation of business data, a business data processor 100 handles these tasks. The processor 100 may not be capable of providing all the collection and generation services required, however, it may delegate tasks to one or more network servers.

[0056] The business data processor 100 is shown as having access to three different servers, an image processor 102, a text to speech server 104, and an announcement server 106. The announcement server is coupled to an announcement database 108. The database may be used to store a plurality of predetermined subscriber announcements which can be readily recalled from the database by the announcement server. After collection and generation of the business data is complete, the data is passed to a response handler 110. The response handler 110 organizes the data and prepares it for transmission by the interface handler.

Claims

1. A method of customizing a network communication protocol, comprising the steps of:

- a) defining one or more customer transaction profiles (98) for a subscriber to said network, each of said profiles being associated with a unique subscriber identification number;
- b) storing said customer transaction profiles in a database (15);
- c) assigning one of said unique subscriber identification numbers to a communication session initiated on said network;
- d) using said assigned subscriber identification number to determine a matching customer transaction profile for said communication session;
- e) accessing said database to retrieve said matching customer transaction profile;
- f) using said matching profile to govern the flow of communications during said communication session;
- g) forming a communication packet (48) according to a message format that is specified within said matching customer transaction profile; and
- h) transmitting said communication packet using a standard packet switching protocol.

2. The method according to claim 1, wherein the step of using said matching profile to govern the flow of communications during said communication session comprises the steps of:

appending a packet header (68) to said communication packet.

3. The method according to claim 2, wherein the step of appending a packet header to said communication packet comprises the steps of:

creating an X.25 packet header; and
appending said X.25 packet header to said communication packet.

4. The method according to claim 2, wherein the step of appending a packet header to communication packet comprises the steps of:

creating an ISDN-PRI packet header; and

appending said ISDN-PRI packet header to said communication packet.

5. The method according to claim 1, further comprising the step of:

5 modifying said customer transaction profile in response to a request from said subscriber to alter the communication flow.

6. An apparatus for providing customizable protocols to users of a communication network, comprising:

10 a) a database (15) for storing one or more customer transaction profiles (98), each said profile being associated with a unique subscriber identification number;
 b) a front end system (50) for assigning one of said subscriber identification numbers ID to a communication session initiated on said network (58), said assigned subscriber ID being used to determine a matching customer transaction profile for said communication session, said matching profile being retrieved from said database and used to manage the flow of communications during said communication session;
 15 c) front end formatting apparatus formatting a communication packet (48) according to a message format that is specified within said matching customer transaction profile; and
 d) front end transmitting apparatus transmitting said communication packet using a standard packet switching protocol.

20 7. The apparatus according to claim 6, wherein said unique subscriber identification number comprises a telephone number (64a-641).

8. The apparatus according to claim 6, wherein each of said customer transaction profiles comprises:

25 one or more message formats (48) that define the format of communications between said subscriber and said network; and
 one or more instructions to control the communication flow between said subscriber and said network.

- 30 9. The apparatus according to claim 6, wherein each of said customer transaction profiles comprises:

one or more input message formats;
 one or more output message formats; and
 one or more instructions to control the communication flow between said subscriber and said network.

- 35 10. The apparatus according to claim 9, wherein each of said one or more input message formats and each of said one or more output message formats comprises:

40 one or more field sizes; and
 one or more field definitions.

11. The apparatus according to claim 6, further comprising:

45 means (24) for coupling said front end system to said subscriber.

12. The apparatus according to claim 6, further comprising:

means (14) for coupling said database to said front end system.

- 50 13. The apparatus according to claim 10, wherein said front end system comprises a computer (100).

14. The apparatus according to claim 6, further comprising:

55 means (10) for modifying said customer transaction profiles.

15. The apparatus of claim 6, further comprising:

e) the front end system having a disk memory (14) for storing said customer transaction profiles (98), a main

memory (16) into which one or more of said customer transaction profiles can be loaded to create one or more loaded profiles; and
f) a means for using said loaded profiles to control the communication flow over said network.

16. The apparatus according to claim 15, wherein each of said unique subscriber identification numbers comprises a telephone number (64a-641).

17. The apparatus according to claim 15, wherein each of said customer transaction profiles comprise:

one or more message formats (48) that define the format of communications between said subscriber and said network (58), each of said one or more message formats including one or more field sizes and one or more field definitions; and
one or more instructions to control the flow of communications over said network.

18. The apparatus according to claim 15, further comprising:

means (24) for coupling said front end system to said subscriber.

19. The apparatus according to claim 15, wherein said front end system is a computer (100).

20. The apparatus according to claim 15, further comprising:

means (10) for modifying said customer transaction profiles.

Revendications

1. Procédé de personnalisation d'un protocole de communication de réseau, comprenant les étapes :

a) de définition d'un ou plusieurs profils de transactions d'abonné (98) pour un abonné audit réseau, chacun desdits profils étant associé à un numéro d'identification d'abonné unique ;
b) de mémorisation desdits profils de transactions d'abonné dans une base de données (15) ;
c) d'attribution d'un desdits numéros d'identification d'abonné uniques à une session de communication lancée sur ledit réseau ;
d) d'utilisation dudit numéro d'identification d'abonné attribué afin de déterminer un profil de transaction d'abonné concordant pour ladite session de communication ;
e) d'accès à ladite base de données afin de recouvrer ledit profil de transaction d'abonné concordant ;
f) d'utilisation dudit profil concordant afin de régir le flux de communications durant ladite session de communication ;
g) de formation d'un paquet de communication (48) conformément à un format de message qui est spécifié dans ledit profil de transaction d'abonné concordant ; et
h) de transmission dudit paquet de communication au moyen d'un protocole de commutation par paquets standard.

2. Procédé selon la revendication 1, dans lequel l'étape d'utilisation dudit profil concordant afin de régir le flux de communications durant ladite session de communication comprend les étapes :

d'ajout d'un paquet d'en-tête (68) audit paquet de communication.

3. Procédé selon la revendication 2, dans lequel l'étape d'ajout d'un en-tête de paquet audit paquet de communication comprend les étapes :

de création d'un en-tête de paquet X.25 ; et
d'ajout dudit en-tête de paquet X.25 audit paquet de communication.

4. Procédé selon la revendication 2, dans lequel l'étape d'ajout d'un paquet d'en-tête au paquet de communication comprend les étapes :

de création d'un en-tête de paquet RNIS-PRI ; et
d'ajout dudit en-tête de paquet RNIS-PRI audit paquet de communication.

- 5 5. Procédé selon la revendication 1, comprenant en outre l'étape :

de modification dudit profil de transaction d'abonné en réponse à une demande dudit abonné afin de changer le flux de communication.

- 10 6. Dispositif pour fournir des protocoles personnalisables à des utilisateurs d'un réseau de communication, comprenant :

a) une base de données (15) pour mémoriser un ou plusieurs profils de transactions d'abonné (98), chaque dit profil étant associé à un numéro d'identification d'abonné unique ;
b) un système frontal (50) pour attribuer l'un desdits numéros d'identification d'abonné ID à une session de communication lancée sur ledit réseau (58), ladite ID d'abonné attribuée étant utilisée pour déterminer un profil de transaction d'abonné concordant pour ladite session de communication, ledit profil concordant étant recouvré depuis ladite base de données et utilisé afin de gérer le flux de communications durant ladite session de communication ;
c) un dispositif de formatage frontal formatant un paquet de communication (48) conformément à un format de message qui est spécifié dans ledit profil de transaction d'abonné concordant ; et
d) un dispositif de transmission frontal transmettant ledit paquet de communication au moyen d'un protocole de commutation par paquets standard.

- 25 7. Dispositif selon la revendication 6, dans lequel ledit numéro d'identification d'abonné unique comprend un numéro de téléphone (64a à 641).

8. Dispositif selon la revendication 6, dans lequel chacun desdits profils de transactions d'abonnés comprend :

un ou plusieurs formats de message (48) qui définissent le format des communications entre ledit abonné et ledit réseau ; et
une ou plusieurs instructions pour commander le flux de communication entre ledit abonné et ledit réseau.

- 30 9. Dispositif selon la revendication 6, dans lequel chacun desdits profils de transactions d'abonnés comprend :

un ou plusieurs formats de message d'entrée ;
un ou plusieurs formats de message de sortie ; et
une ou plusieurs instructions afin de commander le flux de communication entre ledit abonné et ledit réseau.

- 40 10. Dispositif selon la revendication 9, dans lequel chacun desdits un ou plusieurs formats de message d'entrée et chacun desdits un ou plusieurs formats de message de sortie comprend :

une ou plusieurs tailles de champs ; et
une ou plusieurs définitions de champs.

- 45 11. Dispositif selon la revendication 6, comprenant en outre :

un moyen (24) pour coupler ledit système frontal audit abonné.

- 50 12. Dispositif selon la revendication 6, comprenant en outre :

un moyen (14) pour coupler ladite base de données audit système frontal.

13. Dispositif selon la revendication 10, dans lequel ledit système frontal comprend un ordinateur (100).

- 55 14. Dispositif selon la revendication 6, comprenant en outre ;
un moyen (10) pour modifier lesdits profils de transactions d'abonné.

15. Dispositif selon la revendication 6, comprenant en outre :

e) le système frontal ayant une mémoire à disques (14) pour mémoriser lesdits profils de transactions d'abonné (98), une mémoire principale (16) dans laquelle un ou plusieurs desdits profils de transactions d'abonné peuvent être chargés afin de créer un ou plusieurs profils chargés ; et
f) un moyen pour utiliser lesdits profils chargés afin de commander le flux de communication sur ledit réseau.

16. Dispositif selon la revendication 15, dans lequel chacun desdits numéros d'identification d'abonné uniques comprend un numéro de téléphone (64a à 64i).

17. Dispositif selon la revendication 15, dans lequel chacun desdits profils de transactions d'abonnés comprend :

un ou plusieurs formats de message (48) qui définissent le format des communications entre ledit abonné et ledit réseau (58), chacun desdits un ou plusieurs formats de message comportant une ou plusieurs tailles de champs et une ou plusieurs définitions de champs ; et
une ou plusieurs instructions afin de commander le flux de communications sur ledit réseau.

18. Dispositif selon la revendication 15, comprenant en outre :

un moyen (24) pour coupler ledit système frontal audit abonné.

19. Dispositif selon la revendication 15, dans lequel ledit système frontal est un ordinateur (100).

20. Dispositif selon la revendication 15, comprenant en outre ;
un moyen (10) pour modifier lesdits profils de transactions d'abonné.

Patentansprüche

1. Verfahren zum individuellen Anpassen eines Netzwerkkommunikationsprotokolls, das die folgenden Schritte aufweist:

- a) Definition eines Kundenaktionsprofils oder mehrerer Kundenaktionsprofile (98) für einen Abonnenten des Netzwerks, wobei jedes Profil einer eindeutigen Abonnenten-Identifikationsnummer zugeordnet ist;
- b) Speichern der Kundenaktionsprofile in einer Datenbank (15);
- c) Zuteilen einer der eindeutigen Abonnenten-Identifikationsnummern zu einer im Netzwerk begonnenen Kommunikationssitzung;
- d) Verwenden der zugeordneten Abonnenten-Identifikationsnummer zum Bestimmen eines passenden Kundenaktionsprofils für die Kommunikationssitzung;
- e) Zugriff auf die Datenbank, um das passende Kundenaktionsprofil abzurufen;
- f) Verwenden des passenden Profils, um den Kommunikationsfluss während der Kommunikationssitzung zu regeln;
- g) Bilden eines Kommunikationspakets (48) entsprechend einem Nachrichtenformat, das innerhalb des passenden Kundenaktionsprofils spezifiziert ist; und
- h) Übertragen des Kommunikationspakets unter Verwendung eines genormten Paketvermittlungsprotokolls.

2. Verfahren nach Anspruch 1, wobei der Schritt der Verwendung des passenden Profils, um den Kommunikationsfluss während der Kommunikationssitzung zu regeln, die folgenden Schritte aufweist:

Anhängen eines Paketheaders (68) an das Kommunikationspaket.

3. Verfahren nach Anspruch 2, wobei der Schritt des Anhängens eines Paketheaders an das Kommunikationspaket die folgenden Schritte aufweist:

Erzeugen eines X.25-Paketheaders; und
Anhängen des X.25-Paketheaders an das Kommunikationspaket.

4. Verfahren nach Anspruch 2, wobei der Schritt des Anhängens eines Paketheaders an das Kommunikationspaket die folgenden Schritte aufweist:

Erzeugen eines ISDN-PRI-Paketheaders; und
Anhängen des ISDN-PRI-Paketheaders an das Kommunikationspaket.

- 5 5. Verfahren nach Anspruch 1, das weiter den folgenden Schritt aufweist:

Verändern des Kundentransaktionsprofils als Antwort auf eine Forderung des Abonnenten, den Kommunikationsfluss zu ändern.

- 10 6. Vorrichtung zum Liefen individuell anpassbarer Protokolle an Nutzer eines Kommunikationsnetzwerks, die aufweist:

a) eine Datenbank (15) zum Speichern eines Kundentransaktionsprofils oder mehrerer Kundentransaktionsprofile (98), wobei jedes Profil einer eindeutigen Abonnenten-Identifikationsnummer zugeordnet ist;
b) ein Front-End-System (50) zum Zuteilen einer der Abonnenten-Identifikationsnummern ID zu einer Kommunikationssitzung, die im Netzwerk (58) eingeleitet wurde, wobei die zugeteilte Abonnenten-ID verwendet wird, um ein passendes Kundentransaktionsprofil für die Kommunikationssitzung zu bestimmen, wobei das passende Profil aus der Datenbank abgerufen und verwendet wird, um den Kommunikationsfluss während der Kommunikationssitzung zu verwalten;
c) eine das Front-End formatierende Vorrichtung, die ein Kommunikationspaket gemäß einem Nachrichtenformat (48) formatiert, das innerhalb des passenden Kundentransaktionsprofils spezifiziert ist; und
d) eine Front-End-Übertragungsvorrichtung, die das Kommunikationspaket unter Verwendung eines genormten Paketvermittlungsprotokolls überträgt.

- 20 7. Vorrichtung nach Anspruch 6, wobei die eindeutige Abonnenten-Identifikationsnummer eine Telefonnummer (64a-641) enthält.

- 25 8. Vorrichtung nach Anspruch 6, wobei jedes der Kundentransaktionsprofile aufweist:

ein Nachrichtenformat oder mehrere Nachrichtenformate (48), die das Format der Kommunikationen zwischen dem Abonnenten und dem Netzwerk definieren; und
einen Befehl oder mehrere Befehle, um den Kommunikationsfluss zwischen dem Abonnenten und dem Netzwerk zu steuern.

- 30 9. Vorrichtung nach Anspruch 6, wobei jedes Kundentransaktionsprofil aufweist:

ein Eingangsnachrichtenformat oder mehrere Eingangsnachrichtenformate;
ein Ausgangsnachrichtenformat oder mehrere Ausgangsnachrichtenformate; und
einen Befehl oder mehrere Befehle, um den Kommunikationsfluss zwischen Abonnent und Netzwerk zu steuern.

- 35 10. Vorrichtung nach Anspruch 9, wobei jedes eine oder mehrere Eingangsnachrichtenformat(e) und jedes eine oder mehrere Ausgangsnachrichtenformat(e) aufweist:

eine oder mehrere Feldgrößen und
eine oder mehrere Felddefinitionen.

- 40 11. Vorrichtung nach Anspruch 6, die weiter aufweist:

Mittel (24) zum Koppeln des Front-End-Systems mit dem Abonnenten.

- 45 12. Vorrichtung nach Anspruch 6, die weiter aufweist:

Mittel (14) zum Koppeln der Datenbank mit dem Front-End-System.

- 50 13. Vorrichtung nach Anspruch 10, wobei das Front-End-System einen Computer (100) aufweist.

- 55 14. Vorrichtung nach Anspruch 6, die weiter aufweist:

Mittel (10) zum Verändern der Kundentransaktionsprofile.

15. Vorrichtung nach Anspruch 6, die weiter aufweist:

- 5 e) das Front-End-System mit einem Diskettenspeicher (14) zum Speichern der Kundentransaktionsprofile (98), einen Hauptspeicher (16), in den eines oder mehrere der Kundentransaktionsprofile geladen werden können, um ein geladenes Profil oder mehrere geladene Profile zu erzeugen, und
f) eine Einrichtung zur Verwendung der geladenen Profile zur Steuerung des Kommunikationsflusses über das Netzwerk.

10 16. Vorrichtung nach Anspruch 15, wobei jede der eindeutigen Abonnenten-Identifikationsnummern eine Telefonnummer (64a-641) enthält.

17. Vorrichtung nach Anspruch 15, wobei jedes Kundentransaktionsprofil aufweist:

- 15 ein Nachrichtenformat oder mehrere Nachrichtenformate (48), die das Format der Kommunikationen zwischen dem Abonnenten und dem Netzwerk (58) definieren, wobei jedes Nachrichtenformat eine oder mehrere Feldgrößen und eine oder mehrere Felddefinitionen aufweist; und
einen Befehl oder mehrere Befehle zur Steuerung des Kommunikationsflusses über das Netzwerk.

20 18. Vorrichtung nach Anspruch 15, die weiter aufweist:

Mittel (24) zum Koppeln des Front-End-Systems mit dem Abonnenten.

25 19. Vorrichtung nach Anspruch 15, wobei das Front-End-System ein Computer (100) ist.

20. Vorrichtung nach Anspruch 15, die weiter aufweist:

- 30 Mittel (10) zum Verändern der Kundentransaktionsprofile.
